### **Linking Diagenesis To Sequence Stratigraphy**

Sequence stratigraphy is a powerful tool for the prediction of depositional porosity and permeability, but does not account for the impact of diagenesis on these reservoir parameters. Therefore, integrating diagenesis and sequence stratigraphy can provide a better way of predicting reservoir quality.

Diagenesis and sequence stratigraphy have been formally treated as two independent disciplines in sedimentary geology. It was just recently documented that diagenetic alterations such as calcite and dolomite cementation might be distributed at sites coincident with sequence stratigraphic surfaces (Tucker, 1993; Taylor et al., 1995).

The typically independent and isolated methods of diagenesis and sequence stratigraphy, when integrated, can serve as a powerful tool for the understanding and prediction of the distribution of diagenetic alterations of depositional porosity and permeability and of their impact on reservoir quality distribution and evolution for those working in the fields of sedimentary petrology, sequence stratigraphy, and petroleum geology.
